Part 3: Science

Vibrations and Waves

Linear Motion

Thermal Expansion

Vibrations and Waves

- Toolhead is attached to tensioned belts.
- Vibrations are created when the toolhead accelerates.
 - Speeds up.
 - Slows down.
 - Changes direction.
- Belts (strings) + vibrations (waves) = Physics.
- And what does Physics have to say?
 - Motions systems with belts have a dominant **natural frequency**.
 - Think of a guitar string playing a note.

Vibrations and Waves

Let's breakdown what is happening.

- Toolhead excites the belts (adds energy) in the form of vibrations (waves).
- Waves travel along the belts.
 - They interfere and combine with each other. (Superposition principle.)
- In most cases, interference is random.
 - Inconsistent wave patterns.
 - Vibrations stay small and easily dissipate.

Resonance

- At a natural frequency, special interference patterns appear.
- Standing waves.
- Constructive interference.
- Shape of each individual wave aligns and adds together.
- Vibrations grow much larger and last longer.
- This phenomenon is called resonance.

(Animation by Dan Russell)

Resonance

- Resonance is bad for 3D printing.
- Vibrating belts push and pull on the toolhead → Small errors in nozzle position.
- Is there a pattern to these errors?
- **Yes, errors repeat based on the resonant frequency.**
- Imagine writing with pen and paper, and someone bumps your hand at regular intervals.

- Where do you see evidence of repeating errors?
- Sharp corners →
Large accelerations →
Large forces ($F = ma$).
- Which direction was the toolhead moving?
- From left to right.

(Screenshot from
Teaching Tech)

- How can you determine frequency?
- Lookup printing speed in settings.
- Measure distance between repeating patterns.

$$freq = \frac{print_speed}{repeating_dist}$$

(Screenshot from
Teaching Tech)

Input Shaping

- Add extra movements to cancel vibrations.
- Try to create destructive wave interference.
- Opposite of resonance.
- Think noise-canceling headphones.

(Animation, Demo by
ACS Motion Control)

- Shake and Tune Plugin.
- Attach an accelerometer to the toolhead and read vibrations.
- Results from my printer.
- **Purple** → Before Input Shaper
- **Cyan** → After (Estimated)
- Single and narrow peak is ideal because it is easier to fix.
- Typical printing is less than 100 Hz.

Vibrations and Waves

Linear Motion

Thermal Expansion

Speed Limits

I want to print faster.

- *Acceleration: 10,000 mm/s²*
- *Max speed: 300 mm/s*
- *Typical extrusions: 0.4 mm wide, 0.2 mm tall*
- *Max volumetric flow: 22 mm³/s*
- **How can I determine what to upgrade?**
 - Motors? Top speed or acceleration?
 - Max flow (heater and nozzle combo)?

Linear Motion

- What is the distance to reach top speed?
- Starting speed is 5 mm/s.
 - Cornering speed, square corner velocity, or jerk.
 - *Warning:* Small increases will greatly increase vibrations.
- Need 9 mm extrusions to fully accelerate *and* decelerate.
- Does this seem small enough?

$$v^2 = v_0^2 + 2a(x - x_0)$$

$$300^2 = 5^2 + 2 \times 10,000(\textit{dist})$$

$$\textit{dist} = 4.5 \text{ mm}$$

Velocity and Flow

- Can my hotend melt enough plastic at top speed?
- Almost, $275 < 300$.
- Maybe I should upgrade max flow.

$$print_speed = \frac{flow_rate}{cross_section}$$

$$print_speed = \frac{flow_rate}{extrusion_width \times layer_height}$$

$$print_speed = \frac{22}{0.4 \times 0.2}$$

$$print_speed = 275 \text{ mm/s}$$

Finding Limits

- Real life limits are more complex and nuanced.
- *Example:* Printed bolt about an inch long.
- What is going to limit my printer?
- Let PrusaSlicer do all the math!

- Max requested speed **264 mm/s**
- Looks close to the estimate.

- Max actual speed **184 mm/s**

Why is the requested speed non-uniform?

- Adjust speeds according to **visibility**.
- Print slow on the outside to make pretty extrusions.
- Go fast on the inside to save time.

- Max requested flow
22 mm³/s

- Max actual flow
14 mm³/s

Speed Limits

- What is going on?
- My printer does not hit max speed, or max flow.
- Limited by corners on the part and acceleration.

Linear Motion

Thermal Expansion

Thermal Expansion

- Many solid materials expand as they heat up.
- Coefficient of linear expansion.
- *Example:* Bridges use expansion joints to prevent gaps and buckling.
 - Grow between 1 inch and 1 foot.
- Is thermal expansion important for tiny 3D printer nozzles?

(Photo by Matt H Wade on [Wikipedia](#).)

Thermal Expansion

- How much longer does a hot brass nozzle grow?
- Simplified estimate with a 12 mm cylinder.
 - $\Delta T = 150\text{ }^{\circ}\text{C} \rightarrow + 0.034\text{ mm.}$
 - $\Delta T = 300\text{ }^{\circ}\text{C} \rightarrow + 0.068\text{ mm.}$
- Is this enough to be important?
- Yes, it is large enough to affect the first layer.
 - First layers are **very sensitive**.
 - Well known from experience.

- Results from my printer.
- Change temperature then measure nozzle position.
- Does this look like linear expansion?
- Yes, data forms a line.
- My printer uses two probes and calculates a relative offset → Normalized to zero.
- Error bars $\pm$ one standard deviation.

Thermal Expansion of a Brass Nozzle

Thermal Expansion

- Extra 0.1 mm at 280 °C is the same as a small layer!
- What can you do about this?
 - “Heat soak.” Let everything heat up, expand, and wait for equilibrium.
 - Then probe nozzle position.
 - If you skip waiting, first layer is over-squished.
- Print bed needs the same treatment.

Thermal Expansion

- Printers have lots of parts.
- What happens when they expand at different rates?

Hotend Problems

- *Aluminum expands more than brass.*
- Imagine you screw a cold brass nozzle into a cold aluminum heater block.
- Unequal expansion at hot printing temps.
- Aluminum hole expands more than brass nozzle → A tiny gap forms in the threads.
- High pressure from extruding → Filament leaks out.
- Fixed by tightening nozzle at hot printing temps.

(Blob of doom, [reddit post.](#))

Bimetallic Strips

Consider the X and Y axis on a Voron 3D printer.

- Aluminum extrusion frame.
- Stainless-steel linear rail.
- Form a bimetallic strip (bar) when screwed together.

(Voron Trident Manual)

Bimetallic Strips

- *Aluminum expands more than stainless-steel.*
- Straight and flat at room temperature → Bows as temperature increases.
- Simulation for 300 mm beam, $\Delta T = 40^\circ\text{C}$. Almost 0.2 mm deflection.
- Fixed by adding reinforcing plate.
 - Opposing bending force.
 - Stiffer.
